

Energy Efficiency and Rental Prices in the German Housing Market

Econometric Analysis of Energy Efficiency

Group 1: Ahmed Amasha & Begüm Akyüz

Section 1

Introduction

Motivation & Context I

- Energy efficiency has become a key issue in housing markets due to rising energy prices, environmental concerns, and regulation.
- Energy prices increased by **34.7%** in 2022, making heating costs highly relevant for tenants (Destatis, 2023).
- Since **2014**, mandatory Energy Performance Certificates (EPCs) have made energy efficiency transparent and comparable across apartments (BMWf, 2014).
- Previous studies show that energy efficiency is capitalized into single-family house prices in Germany (Taruttis & Weber, 2022).

Motivation & Context II

- This effect varies across housing markets, with weaker capitalization in tight urban markets and stronger effects in rural regions.
- Evidence for rental apartments, especially regarding urban–rural differences, remains limited.
- This study examines how energy efficiency is reflected in advertised rents across urban and rural rental markets.

Research Question

- How is energy efficiency reflected in advertised rent per square meter for rental apartments in Germany?
- Does the relationship between energy efficiency and rent differ between urban (tight) and rural (loose) rental markets?

Section 2

Data

Data Source & Sample

- **Data source:**
ImmobilienScout24 housing advertisements
- **Dataset:**
CampusFile_WM_2022 (cross-sectional)
- **Unit of observation:**
Individual rental apartment listings
- **Sample:**
Rental apartments with valid information on advertised rent per square meter, energy efficiency, and relevant apartment characteristics

Key Variables

- **Outcome variable (dependent variable):**
 - Advertised rent per m²
- **Explanatory variable of interest (independent variable):**
 - Energy efficiency class (A+, A, B, C, D, E, F, G, H)
 - Reference category: **Class C**
- **Control variables (covariates):**
 - Apartment characteristics: living area, number of rooms, construction year, last modernization
 - Amenities: balcony, elevator, fitted kitchen, parking
- **Market classification:**
 - Rental markets are classified as **urban** and **rural** based on administrative district structure
 - **Urban markets:** districts consisting of a single municipality (*kreisfreie Städte*)
 - **Rural markets:** multi-municipality districts (*Landkreise*)

Section 3

Identification Strategy

Conceptual Framework

- Apartment rents are determined by housing characteristics, amenities, and local market conditions.
- Energy efficiency is treated as a quality attribute of rental apartments that may be reflected in advertised rents.

Source of Variation

- Apartments in the dataset differ in their energy efficiency class.
- The analysis compares apartments with different energy efficiency levels across urban and rural rental markets.

Empirical Strategy

- Control for observable apartment characteristics and amenities (e.g. size, rooms, parking).
- Differentiate between urban and rural rental markets using market classification.
- Estimate the conditional relationship between energy efficiency and advertised rent per square meter.
- Examine whether this relationship differs between urban and rural rental markets.

Key Assumption

- After conditioning on observable apartment characteristics and market type (urban vs. rural), remaining differences in rents are associated with differences in energy efficiency.

Limitations

- The cross-sectional and observational nature of the data does not allow causal interpretation.
- Unobserved apartment characteristics and local factors may still affect both energy efficiency and rental prices.

Section 4

Methodology

Estimator and Model Specification

- Model: Log-linear hedonic rent regression estimated by Ordinary Least Squares (OLS)

$$\ln(\text{Rent}_i) = \alpha + \beta \text{EnergyClass}_i + \gamma \mathbf{X}_i + \varepsilon_i$$

- Specifications:
- $\ln(\text{Rent}_i)$: Log rent per square meter.
- EnergyClass_i : Energy class dummies (A+ to H). **Ref: Class C.**
- $\mathbf{X}_i$: Structural controls (size, age, balcony, etc.).
- ε_i : Error term (**Clustered by District** to correct for local price correlation).
- Urban-rural heterogeneity: Model estimated separately for urban and rural rental markets
- Inference: Robust standard errors

Section 5

Result

Descriptive Statistics I

Table 1: Summary Statistics by Region

Region	Obs	Avg Rent (€/sqm)	Avg Size (sqm)	Efficient (%)
rural	12692	9.51	72.1	31.9
urban	13792	10.05	66.3	27.8

Descriptive Statistics II

- Before controls, we see a clear correlation: More efficient energy classes are associated with higher rents.

Rent Distribution by Energy Efficiency Class

Raw data (no controls). Efficient classes tend to have higher median rents.

Source: ImmoScout24 Data

Regression Results

After controlling for confounders, the premium remains significant.

* **A+ / A:** Significant premium (Tenants pay ~15-20% more). * **F / G / H:** Significant discount (Tenants pay less).

The Green Premium: Rent Impact Relative to Class C

Estimates from Hedonic Regression. Bars represent 95% CIs (Clustered SEs).

Note: Classes modelled as categorical dummies to capture non-linear premiums.

Figure 1: Estimated Green Premium (Relative to Class C)

Market Results

Does the market tightness matter?

- **Urban (Red):** Steep gradient. High willingness to pay for efficiency.
- **Rural (Green):** Flat gradient. Efficiency has little impact on price.

Section 6

Discussion & Limitations

Discussion

- The results indicate that energy efficiency is reflected in advertised rental prices, even after controlling for observable apartment characteristics.
- The stronger association in urban rental markets suggests that energy efficiency plays a more prominent role in rental price formation in cities than in rural areas. This pattern is consistent with the idea that tenants in urban markets face higher energy costs and stronger competition for housing, making energy efficiency more important in rental decisions.
- Differences relative to findings for owner-occupied housing markets highlight that the capitalization of energy efficiency can vary across housing tenures and market contexts.

Limitations

- The analysis relies on cross-sectional listing data and therefore identifies associations rather than causal effects. Unobserved apartment or neighborhood characteristics correlated with energy efficiency may partly explain the estimated rent differences.
- Advertised rents may differ from final transaction rents.
- Urban and rural markets are defined using administrative district structure, which may not fully capture differences in market tightness.

Section 7

Conclusion & Outlook

Conclusion

- Energy efficiency is positively associated with advertised rent per square meter for rental apartments in Germany.
- This association is substantially stronger in urban rental markets than in rural markets.
- Energy efficiency therefore appears to play a more prominent role in rental price formation in cities.

Outlook

- **Implications for Practice:**

- For landlords, investments in energy efficiency are more likely to be reflected in higher rents in urban markets than in rural areas.
- For policymakers, market-based incentives for energy-efficient renovations may be more effective in cities, while rural areas may require additional policy support.

- **Implications for Research:**

- Future research could use panel data or policy changes to identify causal effects and better understand urban–rural differences.
